TITLE
THE GAL OPERON OF
STREPTOMYCES

CROSS REFERENCE TO RELATED APPLICATIONS

15 This application is a continuation-in-part of
Serial Number 834,706, filed February 28, 1986, which is
pending.

BACKGROUND OF THE INVENTION

20

This invention relates to a recombinant DNA
molecule comprising the Streptomyces gal operon.

25 Hodgson, J. Gen. Micro., 128, 2417-2430 (1982),
report that Streptomyces coelicolor A3(2) has a glucose
repression system which allows repression at the level of
transcription of the arabinose uptake system, one of the
glycerol uptake systems, and also repression of the
galactose uptake system in wild type strains. There is no
report in Hodgson of actual galactose metabolism by S.
coelicolor A3(2).

30

Okeda et al. Mol. Gen. Genet., 196, 501-507
(1984), report that glucose kinase activity, 2-deoxyglu-
cose-sensitivity, glucose utilization and glucose
repression were all restored to S. coelicolor A3(2) glk
(glucose kinase) mutants transformed by a 3.5 kb DNA
35 fragment which contained the glk gene cloned from S.
coelicolor into a phage vector.

1 Seno et al., Mol. Gen. Genet., 193, 119-128
(1984), report the glycerol (gyl) operon of Streptomyces
coelicolor, and state that such operon is substrate-
inducible and catabolite-repressible.

5 Debouck et al., Nuc. Acids. Res., 13(6), 1841-1853
(1985), report that the gal operon of E. coli consists of
three structurally contiguous genes which specify the
enzymes required for the metabolism of galactose, i.e.,
10 galE (uridine diphosphogalactose-4-epimerase), galT
(galactose-1-phosphate uridylyltransferase) and galK
(galactokinase); that such genes are expressed from a
polycistronic mRNA in the order E, T, K; that the
expression of the promoter distal gene of the operon,
15 galK, is known to be coupled translationally to the galT
gene immediately preceding it; that such translational
coupling results from a structural overlap between the end
of the galT coding sequence and the ribosome binding
region of galK; and that the translational coupling of
20 galT and galK ensures the coordinate expression of these
genes during the metabolism of galactose.

SUMMARY OF THE INVENTION

This invention relates to a recombinant DNA
molecule comprising a Streptomyces gal operon galK gene;
galE gene; galT gene; P2 promoter expression unit, or P2
25 promoter or any functional derivative thereof as well as a
recombinant DNA molecule comprising a Streptomyces gal
operon P1 promoter, P1 promoter regulated region or the
entire gal operon or any regulatable and functional
derivative thereof.

30 This invention also relates to a recombinant DNA
molecule comprising the Streptomyces gal operon or any
regulatable and functional derivative thereof and a
functional DNA molecule operatively linked to such operon;
a recombinant DNA vector comprising and such DNA molecule,
35 and, optionally, additionally comprising a replicon; a
method of preparing a host cell transformed with such

1 vector; the transformed host prepared by such method; a
method of expressing such functional DNA sequence which
comprises cultivating such transformed host under suitable
5 conditions such that the functional DNA sequence is
expressed; and to a method of regulating the expression of
such functional DNA sequence which comprises cultivating
such transformed host under conditions which regulate such
expression.

10 This invention also relates to a recombinant DNA
molecule comprising the Streptomyces gal operon P2
promoter expression unit or any functional derivative
thereof and a functional DNA molecule operatively linked
to such unit; a recombinant DNA vector comprising such DNA
15 molecule, and, optionally, additionally comprising a
replicon; a method of preparing a host cell transformed
with such vector; the transformed host prepared by such
method; and to a method of expressing such functional DNA
sequence which comprises cultivating such transformed host
20 under suitable conditions such that the functional DNA
sequence is expressed.

This invention also relates to a recombinant DNA
molecule comprising the Streptomyces gal operon P1
promoter regulated region or any regulatable and
functional derivative thereof and a functional DNA
25 molecule operatively linked to such region; a recombinant
DNA vector comprising such DNA molecule, and, optionally,
additionally comprising a replicon; a method of preparing
a host cell transformed with such vector; the transformed
host prepared by such method; a method of expressing such
30 functional DNA sequence which comprises cultivating such
transformed host under suitable conditions such that the
functional DNA sequence is expressed; and to a method of
regulating the expression of such functional DNA sequence
which comprises cultivating such transformed host under
35 conditions which regulate such expression.

This invention also relates to a recombinant DNA

1 molecule comprising the Streptomyces gal operon P1
promoter or any regulatable and functional derivative
thereof and a foreign functional DNA molecule operatively
linked to such region; a recombinant DNA vector comprising
5 such DNA molecule, and, optionally, additionally
comprising a replicon; a method of preparing a host cell
transformed with such vector; the transformed host
prepared by such method; a method of expressing such
functional DNA sequence which comprises cultivating such
10 transformed host under suitable conditions such that the
functional DNA sequence is expressed; and to a method of
regulating the expression of such functional DNA sequence
which comprises cultivating such transformed host under
conditions which regulate such expression.

15 This invention also relates to a recombinant DNA
molecule comprising the Streptomyces gal operon P2
promoter or any functional derivative thereof and a
foreign functional DNA molecule operatively linked to such
region; a recombinant DNA vector comprising such DNA
20 molecule, and, optionally, additionally comprising a
replicon; a method of preparing a host cell transformed
with such vector; the transformed host prepared by such
method; and to a method of expressing such functional DNA
sequence which comprises cultivating such transformed host
25 under suitable conditions such that the functional DNA
sequence is expressed.

This invention also relates to a method of
enabling a non-galactose utilizing host microorganism or
cell to utilize galactose which comprises transforming
30 such host with a recombinant DNA molecule comprising a
Streptomyces gal operon or any portion of the Streptomyces
gal operon, or any functional derivative thereof, which is
adequate to enable such transformed host to utilize
galactose, This invention also relates to the recombinant
35 DNA vector employed in such method and to the host
prepared by such method.

1

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 represents a restriction endonuclease map of the Streptomyces lividans 1326 galactose (gal) operon and indicates approximate locations for structural genes and promoters within the operon.

5

Figure 2 represents a restriction endonuclease map of plasmid pK21.

10

Figure 3 represents a comparison of the restriction endonuclease maps of the S. lividans gal operon and a restriction fragment containing the S. coelicolor galK gene.

DETAILED DESCRIPTION OF THE INVENTION

15

It has now been discovered that the Streptomyces genome contains a operon for the metabolism of galactose (i.e., a gal operon) which comprises three structural genes (galT, galE and galK) and two promoters (P1 and P2). The galT gene product is known as galactose-1-phosphate uridylyltransferase (transferase), the galE gene product is known as uridine diphosphogalactose-4-epimerase (epimerase), and the galK gene product is known as galactose-1-kinase (galactokinase). The function of the gene products of galT, galE and galK in galactose metabolism in Streptomyces is explained by the following diagram:

20

25

1. galactose + ATP galactokinase
galactose-1-phosphate + ADP
2. galactose-1-phosphate + UDP-glucose transferase
UDP-galactose + glucose-1-phosphate
3. UDP-galactose epimerase UDP-glucose

30

By the term "promoter" is meant any region upstream of a structural gene which permits binding of RNA polymerase and transcription to occur.

35

1 By the term "structural gene" is meant a coding
sequence for a polypeptide which serves to be the template
for the synthesis of mRNA.

5 By the term "operon" is meant a group of closely
linked genes responsible for the synthesis of one or a
group of enzymes which are functionally related as members
of one enzyme system. An operon comprises an operator
gene, a number of structural genes (equivalent to the
10 number of enzymes in the system) and a regulator gene. By
"operator" or "operator gene" is meant a DNA sequence
which controls the biosynthesis of the contiguous
structural gene(s) within an operon. By "regulator gene"
is meant a gene which controls the operator gene in an
operon through the production of a repressor which can be
15 either active (enzyme induction) or inactive (enzyme
repression). The transcription of the structural gene(s)
in an operon is switched on or off by the operator gene
which is itself controlled in one or more of three ways:
1) in inducible enzyme systems, the operator is switched
20 off by a repressor produced by the regulator gene and
which can be inactivated by some metabolite or signal
substance (an inducer) coming from elsewhere in the cell
or outside the cell, so that the presence of the inducer
results in the operon becoming active; or 2) in repressed
25 enzyme systems, the operator is switched off by a
repressor-corepressor complex which is a combination of an
inactive repressor produced by the regulator gene with a
corepressor from elsewhere, so that the presence of the
corepressor renders the operon inactive; or 3) in
30 activated gene systems, the promoter is switched on by an
activator produced by a regulator gene which can be
activated by some metabolic or signal substance.

The Streptomyces gal operon is naturally present
in the Streptomyces genome.

35 By the term "Streptomyces gal operon" is meant
that region of the Streptomyces genome which comprises the

1 P1 promoter, P2 promoter, galT, galE and galK structural
genes and any other regulatory regions required for
transcription and translation of such structural genes.

5 By the term "regulatory region" is meant a DNA
sequence, such as a promoter or operator, which regulates
transcription of a structural gene.

The following model is suggested for gene
expression within the Streptomyces gal operon. The P1
10 promoter is a galactose inducible promoter (i.e., it is
induced in the presence of galactose and repressed in the
presence of glucose). According to S1 data, the P2
promoter is constitutive, i.e., it is "turned on"
regardless of the presence or absence of galactose or any
other carbon source.

15 A cosmid library was constructed for Streptomyces
lividans 1326 DNA by using cosmid pJW357 (which encodes
the ability to replicate in both Streptomyces and E.
coli). This library was then transfected into E. coli K21
20 which is a derivative of the E. coli strain MM294 which
contained a bacteriophage P1 transduced galactokinase
(galK) mutation. Transfected cells were plated under
media conditions which select for both the presence of the
cosmid and the presence of an active galK gene. Weakly
positive colonies were isolated and the cosmid DNA derived
25 from these colonies was transformed into the K21 strain.
These transformations yielded two cosmids which
consistently produced positive growth with galactose as
the only carbon source. These galK⁺ cosmids were then
transformed into a Streptomyces host (i.e., Streptomyces
30 lividans 1326-12K) which had been isolated by the
inventors of the subject invention as unable to grow on
medium in which galactose was the only carbon source by
using 2-deoxy-galactose selection [see, Brawner et al.,
Gene, 40 191 (1985), in press]. Under conditions which
35 differentiate strains able and unable to produce

1

galactokinase, only one of the cosmids caused the Streptomyces lividans 1326-12K host to become galK⁺.

5 Further studies have demonstrated that this cosmid encodes a gene with galactokinase activity. Additional studies, including DNA sequence analysis and protein studies demonstrate that this Streptomyces gene shares homology with the E. coli and yeast galactokinase genes. Regulation studies indicate that the cosmid encoded
10 galactokinase gene regulated in the same manner as the chromosome encoded gene.

A. S. lividans gal operon was originally isolated from a ca. 9 kilobase (Kb) region of Streptomyces lividans 1326. The ca. 9 Kb region of Streptomyces lividans 1326
15 containing the Streptomyces gal operon has been mapped substantially as follows in Table A. By "substantially" is meant (i) that the relative positions of the restriction sites are approximate, (ii) that one or more restriction sites can be lost or gained by mutations not
20 otherwise significantly affecting the operon, and (iii) that additional sites for the indicated enzymes and, especially for enzymes not tested, may exist. The restriction enzymes used herein are commercially available. All are described by Roberts, Nuc. Acids.
25 Res., 10(5): p117 (1982).

Microorganisms of the genus Streptomyces have historically been used as a source of antibiotics for the pharmaceutical industry. Consequently, the technical skills necessary to scale-up the production of biological products using Streptomyces as the vehicle for the production of such products are presently available. However, before Streptomyces can be used as a vehicle for the production of bioactive molecules using the new recombinant DNA technologies, there is a need to define regulatory elements in Streptomyces analogous to those which have proved useful in E. coli. These regulatory elements include ribosomal binding sites and regulated transcriptional elements.

The existence of a galE, galT or galK gene or gene product or gal operon in Streptomyces has not been previously reported. The instant invention, i.e., the cloning of the Streptomyces gal operon, enables construction of regulatable expression/cloning vectors in Streptomyces, other actinomycetes, and other host organisms. Furthermore, the instant invention led to the discovery that the Streptomyces gal operon is

30

35

1 polycistronic. perhaps the most important feature of the
cloning of the Streptomyces gal operon is the observation
that there are sequences essential for regulation of the
Streptomyces galK gene. Direct analogy to the initial use
5 of the lac promoter from E. coli as an expression system
can be made. In fact, Brosius et al., Proc. Natl. Acad.
Sci. USA, 81, 6929-6933 (1984), utilized the regulatory
elements of the E. coli lac promoter to regulate the
exceptionally strong E. coli ribosomal promoters. Because
10 it is likely that the Streptomyces gal operon ribosomal
promoters are also exceptionally strong, such promoters
enable the construction of regulatable expression vectors
which will be very useful in Streptomyces, other
actinomycetes, and other host organisms. The instant
15 invention also enabled the unexpected discovery that the
2-deoxygalactose selection which has been used in E. coli
to select for galK mutants also operates in Streptomyces
to select for galK mutants [see, Brawner et al., Gene 40,
191 (1985), in press]. This observation, combined with
20 the ability to clone the Streptomyces galK gene and the
promoter and regulatory regions required for its
transcription and translation on a cosmid, as described
herein, allows the direct insertion of any structural gene
into the chromosomally located galK gene of Streptomyces
25 by homologous recombination. This manipulation will allow
molecular biologists to stably insert DNA fragments of
interest into the Streptomyces chromosome. Such an
approach will allow researchers to tag or mark a
Streptomyces strain of interest or to insert expression
30 cassettes into the organism without the need of
maintaining an antibiotic selection such as that presently
required by most Streptomyces expression vectors.

This invention relates to a recombinant DNA
molecule comprising the Streptomyces gal operon or any
35 regulatable and functional derivative thereof.

1 By "regulatable and functional derivative" is meant any
 derivative of the Streptomyces gal operon which functions
 in substantially the same way as the naturally occurring
Streptomyces gal operon in terms of regulatable production
 5 of the galT, galE and galK gene products. Such
 derivatives include partial sequences of the gal operon,
 as well as derivatives produced by modification of the gal
 operon coding sequence. Techniques for modifying the gal
 operon which are known in the art include, for example,
 10 treatment with chemical mutagens, irradiation or direct
 genetic engineering, such as by inserting, deleting or
 substituting nucleic acids by the use of enzymes or
 recombination techniques. The naturally occurring
Streptomyces gal operon can be isolated from any galactose
 15 utilizing Streptomyces strain by employing the techniques
 described herein. Numerous strains of various
Streptomyces species are publicly available from many
 sources. For example, the American Type Culture
 Collection, Rockville, Maryland, U.S.A. has approximately
 20 400 different species of Streptomyces available to the
 public. The ability of a particular strain of
Streptomyces to utilize galactose can be readily
 determined by conventional techniques, such as by growing
 such strain on a medium containing galactose as the sole
 25 carbon source. The preferred Streptomyces species from
 which to isolate a gal operon include S. lividans, S.
coelicolor, S. azureus and S. albus, S. carzinostaticus,
S. antifibrinolyticus and S. longisporus. S. lividans is
 most preferred. The Streptomyces gal operon, and smaller
 30 portions thereof, is useful as a nucleic acid probe to
 obtain homologous sequences from other cells and
 organisms. The Streptomyces gal operon is also useful as
 a selection marker in an appropriate host mutant, and for
 providing regulatory elements. By "appropriate host
 35 mutant" is meant a host which does not utilize galactose

1 because it (a) does not contain a gal operon or (b)
contains a nonfunctional gal operon, or (c) contains a
defect within a homologous structural gene or regulatory
region comprised by the Streptomyces gal operon such as a
5 defective P1 promoter, P2 promoter, galT gene, galK gene
and/or galE gene. Thus, a recombinant DNA molecule
(comprising the Streptomyces gal operon and a foreign
functional DNA sequence operatively linked thereto), which
can be prepared by conventional techniques, can be
10 transformed into an appropriate host mutant by
conventional techniques for incorporation into the host
genome by homologous recombination to enable regulatable
expression of the foreign functional DNA sequence without
the need of maintaining an expensive antibiotic
15 selection. Such operon may therefore also be incorporated
on recombinant DNA expression vectors for regulatable
expression of a foreign functional DNA sequence
operatively linked to such operon in an appropriate host
mutant transformed with such vector without the need of
20 maintaining an expensive antibiotic selection. Such
operon is also useful for transforming those cells,
viruses and microorganisms, such as strains of
Streptomyces, other actinomycetes, and other prokaryotic
organisms, such as gal⁻ E. coli strains, which do not
| 25 utilize galactose into galactose utilizing strains. Such
transformation may have pleiotrophic effects on the
transformed host. By the term "functional DNA sequence"
is meant any discrete region of DNA derived directly or
indirectly from Streptomyces or any other source which
30 functions in a host organism transformed therewith as a
gene expression unit, structural gene, promoter or a
regulatory region. Preferred functional DNA sequences
include those coding for polypeptides of pharmaceutical
importance, such as, but not limited to, insulin, growth
35 hormone, tissue plasminogen activator, alpha -1-anti-
trypsin or antigens used in vaccine production. By the

1 term "foreign functional DNA sequence" is meant a
functional DNA sequence not derived from the Streptomyces
gal operon coding region.

5 This invention also relates to a recombinant DNA
molecule comprising the Streptomyces gal operon P2
promoter expression unit or any functional derivative
thereof. By the term "P2 promoter expression unit" is
meant that region of the Streptomyces gal operon
comprising the Streptomyces gal operon P2 promoter, galE
10 and galK structural genes and any other regulatory regions
required for transcription and translation of such
structural genes. By "functional derivative" is meant any
derivative of the Streptomyces gal operon P2 promoter
expression unit which functions in substantially the same
15 way as the naturally occurring region in terms of
production of the Streptomyces gal operon galE and galK
gene products. Such derivatives include partial sequences
of the Streptomyces gal operon P2 promoter expression
unit, as well as derivatives produced by modification of
20 the Streptomyces gal operon P2 promoter expression unit
coding sequence. Techniques for effecting such
modification are known in the art, and some have been
outlined above. The naturally occurring Streptomyces gal
operon P2 promoter expression unit can be isolated from
25 the naturally occurring Streptomyces gal operon by
conventional techniques. The Streptomyces gal operon P2
expression unit is useful as a selection marker in an
appropriate host mutant and for providing regulatory
elements. By "appropriate host mutant" is meant a host
30 which does not utilize galactose because it contains a
defect within a homologous structural gene or regulatory
region comprised by the Streptomyces P2 promoter
expression unit such as a defective P2 promoter, galE gene
and/or galK gene. Thus, a recombinant DNA molecule
35 (comprising the Streptomyces gal operon P2 promoter
expression unit and a foreign functional DNA sequence .

1 operatively linked thereto), which can be prepared by
conventional techniques, can be transformed into an
appropriate host mutant by conventional techniques for
incorporation into the host genome by homologous
5 recombination to enable constitutive expression of the
foreign functional DNA sequence without the need of
maintaining an expensive antibiotic selection. Such
expression unit may also be incorporated on recombinant
DNA expression vectors for constitutive expression of
10 foreign functional DNA sequences. The Streptomyces gal
operon P2 promoter expression unit is also useful for
complementation of an appropriate host mutant which can
then be used for constitutive expression of a foreign
functional DNA sequence operatively linked to such
15 expression unit in an appropriate host mutant transformed
with such vector without the need of maintaining an
expensive antibiotic selection.

This invention also relates to a recombinant DNA
molecule comprising the Streptomyces gal operon P1
20 promoter regulated region or any regulatable and
functional derivative thereof. By the term "P1 promoter
regulated region" is meant that region of the Streptomyces
gal operon comprising the Streptomyces gal operon P1
promoter, galT, galE and galK structural genes and any
25 other regulatory regions required for transcription and
translation of such structural genes. By "regulatable and
functional derivative" is meant any derivative of the
Streptomyces gal operon P1 promoter regulated region which
functions in substantially the same way as the naturally
30 occurring region in terms of regulatable production of the
Streptomyces gal operon galT, galE and galK gene
products. Such derivatives include partial sequences of
the Streptomyces gal operon P1 promoter regulated region,
as well as derivatives produced by modification of the
35 Streptomyces gal operon P1 promoter regulated region
coding sequence. Techniques for effecting such

1 modification are known in the art, and some have been
outlined above. The naturally occurring Streptomyces gal
operon P1 promoter regulated region can be isolated from
the naturally occurring Streptomyces gal operon by
5 conventional techniques, such as by excising the P2
promoter from the naturally occurring Streptomyces gal
operon or inactivating the P2 promoter by a point mutation
or by inserting a foreign DNA sequence within the
promoter. The Streptomyces gal operon P1 promoter
10 regulated region is useful for the utilities outlined
above for the Streptomyces gal operon.

This invention also relates to a recombinant DNA
molecule comprising the Streptomyces gal operon P2
promoter or any functional derivative thereof. By
"functional derivative" is meant any derivative of the
15 Streptomyces gal operon P2 promoter which functions in
substantially the same way as the naturally occurring P2
promoter in terms of enabling the binding of RNA
polymerase thereto and transcription of a functional DNA
sequence operatively linked to such promoter. Such
20 derivatives include partial sequences of the Streptomyces
gal operon P2 promoter, as well as derivatives produced by
modification of the gal operon P2 promoter coding
sequence. Techniques for effecting such modification are
known in the art, and some have been outlined above. The
25 naturally occurring Streptomyces gal operon P2 promoter
can be isolated from the naturally occurring Streptomyces
gal operon by conventional techniques. A recombinant DNA
molecule (comprising the Streptomyces gal operon P2
promoter and a foreign functional DNA sequence operatively
30 linked thereto), which can be prepared by conventional
techniques, can be transformed into an appropriate host
mutant by conventional techniques for incorporation into
the host genome by homologous recombination to enable
constitutive expression of the foreign functional DNA
35 sequence. The Streptomyces gal operon P2 promoter is also

1 useful for incorporation into recombinant DNA expression
vectors for constitutive expression of a foreign
functional DNA sequence operatively linked thereto in
viruses and eukaryotic or prokaryotic cells or organisms,
5 especially in Streptomyces or other actinomycetes,
transformed with such vector.

This invention also relates to a recombinant DNA
molecule comprising the Streptomyces gal operon P1
promoter or any regulatable and functional derivative
10 thereof. By "regulatable and functional derivative" is
meant any derivative of the Streptomyces gal operon P1
promoter which functions in substantially the same way as
the naturally occurring P1 promoter in terms of enabling
the binding of RNA polymerase thereto and regulating the
15 transcription of a functional DNA sequence operatively
linked to such promoter. Such derivatives include partial
sequences of the Streptomyces gal operon P1 promoter, as
well as derivatives produced by modification of the gal
operon P1 promoter coding sequence. Techniques for
20 effecting such modification are known in the art, and some
have been outlined above. The naturally occurring
Streptomyces gal operon P1 promoter can be isolated from
the naturally occurring Streptomyces gal operon by
conventional techniques. A recombinant DNA molecule
25 (comprising the Streptomyces gal operon P1 promoter and a
foreign functional DNA sequence operatively linked
thereto), which can be prepared by conventional
techniques, can be transformed into an appropriate host
mutant by conventional techniques for incorporation into
30 the host genome by homologous recombination to enable
regulatable expression of the foreign functional DNA
sequence. The Streptomyces gal operon P1 promoter is also
useful for incorporation into recombinant DNA expression
vectors for regulatable expression of a foreign functional
35 DNA sequence operatively linked thereto in viruses and
eukaryotic or prokaryotic cells or organisms, especially

1 Streptomyces or other actinomycetes, transformed with such vector.

5 This invention also relates to a recombinant DNA molecule comprising the Streptomyces gal operon galE, galT or galK gene, or any functional derivative thereof. By "functional derivative" is meant any derivative of the Streptomyces gal operon galE, galT or galK gene which functions in substantially the same way as the naturally occurring gene in terms of production of an active galE, galT, or galK type gene product. Such derivatives include partial sequences of the Streptomyces gal operon galE, galT, or galK gene, as well as derivatives produced by modification of the gal operon sequence. Techniques for effecting such modification are known in the art, and some have been outlined above. The naturally occurring Streptomyces gal operon galE, galT and/or galK gene can be isolated from the naturally occurring Streptomyces gal operon by conventional techniques. The Streptomyces gal operon galE, galT and/or galK gene can be used as a selection marker in an appropriate host mutant. By "appropriate host mutant" is meant a host which does not utilize galactose because it contains a defect within a homologous galE, galT and/or galK gene. Thus, a recombinant DNA molecule (comprising the Streptomyces gal operon galE, galT and/or galK gene and a foreign functional DNA sequence, both of which are operatively linked to appropriate regulatory region), which can be prepared by conventional techniques, can be transformed into an appropriate host mutant by conventional techniques for incorporation into the host genome by homologous recombination to enable detection of transformants without the need of maintaining an expensive antibiotic selection. Likewise, a recombinant DNA vector comprising the Streptomyces gal operon galE, galT and/or galK gene and a foreign functional DNA sequence, both of which are operatively linked to appropriate regulatory

1 regions, as well as a replicon, can be transformed into an
appropriate host mutant by conventional techniques to
enable detection of transformants without the need of
maintaining an expensive antibiotic selection. The
5 Streptomyces gal operon galE, galK and/or galT gene is
also useful for complementation of an appropriate host
mutant.

The Streptomyces gal operon galE gene is also
useful for providing a ribosome binding site and
10 initiation codon which can be fused to a foreign
functional DNA sequence to enable the expression of such
coding sequence when incorporated into an appropriate
expression vector and transformed into an appropriate
host. If such foreign functional DNA sequence is fused to
15 the galE gene ribosome binding site and initiation codon
in a recombinant DNA expression vector comprising the
Streptomyces gal operon P2 promoter expression unit, or
the entire gal operon, such DNA sequence will be
constitutively expressed when such vector is transformed
20 into an appropriate host organism. If such DNA sequence
is fused to the galE gene ribosome binding site and
initiation codon in a recombinant DNA expression vector
comprising the Streptomyces gal operon P2 promoter
regulated region, expression of such DNA sequence can be
25 regulated when such vector is transformed into an
appropriate host organism by controlling the presence or
absence of galactose or glucose.

The Streptomyces gal operon galT gene is also
useful for providing a ribosome binding site and
30 initiation codon which can be fused to a foreign
functional DNA sequence to enable the expression of such
coding sequence when incorporated onto an appropriate
expression vector and transformed into an appropriate
host. If such DNA sequence is fused to the galT gene
35 ribosome binding site and initiation codon in a
recombinant DNA expression vector comprising the

1 Streptomyces gal operon P1 promoter regulated region, or
the entire gal operon, expression of such coding sequence
can be regulated in a host transformed with such vector as
outlined above.

5 This invention also relates to a recombinant DNA
vector comprising a replicon, Streptomyces gal operon, or
a functional and regulatable derivative thereof, and a
foreign functional DNA sequence operatively linked to such
operon. Such vector can be prepared by conventional
10 techniques. The replicon employed should be one known for
its ability to stably and extrachromosomally, maintain a
vector in the host organism which is to be the host
transformed with the vector.

15 This invention also relates to a transformed host
microorganism comprising a recombinant DNA vector wherein
said vector contains a replicon, the Streptomyces gal
operon, or a functional and regulatable derivative
thereof, and a foreign functional DNA sequence operatively
linked to such operon; and to the method of preparing such
20 host which comprises transforming an appropriate host
microorganism with such vector. Appropriate host
microorganisms which may be employed in the method of this
invention include viruses, and eukaryotic and prokaryotic
cells or organisms, especially actinomycetes, such as
25 those of the genus Streptomyces. The most preferred host
microorganisms belong to the genus Streptomyces.

Preferred species of Streptomyces include Streptomyces
lividans, S. coelicolor, S. azureus and S. albus.

30 Transformation of such host microorganism with such vector
can be accomplished using conventional techniques such as
the method of Chater et al., Curr. Top. Micro. Imm., 96,
69-95 (1982). This invention also related to a method of
expressing the functional DNA sequence contained by such
transformed host of this invention which comprises
35 cultivating such transformed host under suitable
conditions such that the functional DNA sequence is

1 expressed. By "suitable conditions" is meant those
conditions which will allow the host to grow and which
enable the expression of the functional DNA sequence.
Such suitable conditions can be determined by one of skill
5 in the art using conventional techniques and will depend
on various factors, such as the host organism employed and
the functional DNA sequence to be expressed. This
invention is also related to a method of regulating the
expression of the functional DNA sequence contained by
10 such transformed host which comprises cultivating a
transformed host containing such functional DNA sequence
under appropriate conditions such that its expression is
regulatable. By "appropriate conditions" is meant those
conditions which enable the Streptomyces gal operon (and
15 thus the foreign functional DNA sequence) to be
regulatable. By "regulatable" is meant responsive to the
presence of galactose or its metabolites and the presence
of glucose or its metabolites in the growth media of the
transformed host cell. Such regulation can be carried out
20 by addition or deletion of galactose or glucose to the
transformed host's culture medium. The optimal levels of
galactose and/or glucose for up or down-regulation of the
expression of the foreign functional DNA coding sequence
by the transformed host of this invention can be readily
25 determined by one of skill in the art using conventional
techniques.

This invention also relates to a recombinant DNA
vector comprising a replicon, a Streptomyces gal operon P2
30 promoter expression unit, or a functional derivative
thereof, and a foreign functional DNA sequence operatively
linked to such unit. Such a vector can be prepared by
conventional techniques. The replicon employed should be
one known for its ability to stably, and extra-
chromosomally, maintain a vector in the host organism
35 which is to be transformed with the vector.

1 This invention also relates to a transformed host
microorganism comprising a recombinant DNA vector wherein
said vector contains a replicon, the Streptomyces gal
operon P2 promoter expression unit, or a functional
5 derivative thereof, and a foreign functional DNA sequence
operatively linked to such unit; and to the method of
preparing such host which comprises transforming an
appropriate host microorganism with such vector. By the
term "operatively linked" is meant that a functional DNA
10 sequence is transcriptionally or translationally linked to
an expression control sequence (i.e., the Streptomyces gal
operon, P2 promoter expression unit, P1 promoter regulated
region, P1 promoter or P2 promoter) in such a way so that
the expression of the functional DNA sequence is under
15 control of the expression control sequence. Thus, for
example, a foreign functional DNA sequence can be
transcriptionally or translationally linked to the
Streptomyces gal operon by inserting such operon within
the Streptomyces gal operon P1 or P2 promoter transcript.
20 By the term "replicon" is meant that region of DNA on a
plasmid which functions to maintain, extrachromosomally,
such plasmid in a host microorganism or cell transformed
therewith. It has also been discovered that the
Streptomyces gal operon, and smaller portions thereof, is
25 useful as a nucleic acid probe to obtain homologous
sequences from other cells and organisms. Appropriate
host microorganisms which may be employed in the method of
this invention include any virus or eukaryotic or
prokaryotic cell or organism, especially any actinomycetes
30 such as those of the genus Streptomyces. The most
preferred host microorganisms belong to the genus
Streptomyces. Preferred species of Streptomyces include
Streptomyces lividans, S. coelicolor, S. azureus and S.
albus. Transformation of such host microorganism with
35 such vector can be accomplished using conventional

1 techniques such as the method of Chater et al., Curr. Top.
2 Micro. Imm., 96, 69-95 (1982). This invention also
3 related to a method of expressing the functional DNA
4 sequence contained by such transformed host of this
5 invention which comprises cultivating such transformed
6 host under suitable conditions such that the functional
7 DNA sequence is expressed. By "suitable conditions" is
8 meant those conditions which will allow the host to grow
9 and which enable the expression of the functional DNA
10 sequence. Such suitable conditions can be determined by
11 one of skill in the art using conventional techniques and
12 will depend on various factors, such as the host organism
13 employed and the functional DNA sequence to be expressed.

14 This invention also relates to a recombinant DNA
15 vector comprising a replicon, a Streptomyces gal operon P1
16 promoter regulated region, or a functional and regulatable
17 derivative thereof, and a foreign functional DNA sequence
18 operatively linked to such region. Such a vector can be
19 prepared by conventional techniques. The replicon
20 employed should be one known for its ability to stably and
21 extrachromosomally maintain a vector in the host organism
22 which is to be the host transformed with the vector.

23 This invention also relates to a transformed host
24 microorganism comprising a recombinant DNA vector wherein
25 said vector contains a replicon, a Streptomyces gal operon
26 P1 promoter regulated region, or a functional and
27 regulatable derivative thereof, and a foreign functional
28 DNA sequence operatively linked to such region; and to the
29 method of preparing such host which comprises transforming
30 an appropriate host microorganism with such vector.
31 Appropriate host microorganisms which may be employed
32 include any virus or eukaryotic or prokaryotic cell or
33 organism especially actinomycetes such as those of the
34 genus Streptomyces. The most preferred host
35 microorganisms belong to the genus Streptomyces.

1 Preferred species of Streptomyces include Streptomyces
lividans, S. coelicolor, S. azureus and S. albus.

Transformation of such host microorganism with such vector
can be accomplished using conventional techniques such as
5 the method of Chater et al., Curr. Top. Micro. Imm., 96,
69-95 (1982). This invention also related to a method of
expressing the foreign functional DNA sequence contained
by such transformed host of this invention which comprises
cultivating such transformed host under suitable
10 conditions such that the functional DNA sequence is
expressed. By "suitable conditions" is meant those
conditions which will allow the host to grow and which
enable the expression of the functional DNA sequence.

Such suitable conditions can be determined by one of skill
15 in the art using conventional techniques and will depend
on various factors, such as the host organism employed and
the functional DNA sequence to be expressed. This
invention also related to a method of regulating the
expression of the functional DNA sequence contained by
20 such transformed host which comprises cultivating a
transformed host containing such functional DNA sequence
under appropriate conditions such that its expression is
regulatable. By "appropriate conditions" is meant those
conditions which enable the Streptomyces gal operon P1
25 promoter regulated region (and thus the foreign functional
DNA sequence) to be regulatable. By "regulatable" is
meant responsive to the presence or absence of galactose
or its metabolites and the presence or absence of glucose
or its metabolites in the growth media of the transformed
30 host cell. Such regulation can be carried out by addition
or deletion of galactose or glucose to the transformed
host's culture medium.

This invention also relates to a recombinant DNA
vector comprising a replicon, a Streptomyces gal operon P2
35 promoter, or a functional derivative thereof, and a
foreign functional DNA sequence operatively linked to such

1 promoter. Such a vector can be prepared by conventional
techniques. The replicon employed should be one known for
its ability to stably and extrachromosomally maintain a
vector in the host organism which is to be the host
5 transformed with the vector.

This invention also relates to a transformed host
microorganism comprising a recombinant DNA vector wherein
said vector contains a replicon, a Streptomyces gal operon
P2 promoter, or a functional derivative thereof, and a
10 foreign functional DNA sequence operatively linked to such
region; and to the method of preparing such host which
comprises transforming an appropriate host microorganism
with such vector. Appropriate host microorganisms which
may be employed include actinomycetes such as those of the
15 genus Streptomyces. The most preferred host
microorganisms belong to the genus Streptomyces.
Preferred species of Streptomyces include Streptomyces
lividans, S. coelicolor, S. azureus and S. albus.
Transformation of such host microorganism with such vector
20 can be accomplished using conventional techniques such as
the method of Chater et al., Curr. Top. Micro. Imm., 96,
69-95 (1982). This invention also related to a method of
expressing the foreign functional DNA sequence contained
by such transformed host of this invention which comprises
25 cultivating such transformed host under suitable
conditions such that the functional DNA sequence is
expressed. By "suitable conditions" is meant those
conditions which will allow the host to grow and which
enable the expression of the functional DNA sequence.
30 Such suitable conditions can be determined by one of skill
in the art using conventional techniques and will depend
on various factors, such as the host organism employed and
the functional DNA sequence to be expressed.

This invention also relates to a recombinant DNA
35 vector comprising a replicon, Streptomyces gal operon P1
promoter, or any regulatable and functional derivative

1 thereof, and a foreign functional DNA sequence operatively
link d to such region. Such a vector can be prepared by
conventional techniques. The replicon employed should be
one known for its ability to stably and extrachromosomally
5 maintain a vector in the host organism which is to be the
host transformed with the vector.

This invention also relates to a transformed host
microorganism comprising a recombinant DNA vector wherein
said vector contains a replicon, the Streptomyces gal
10 operon P1 promoter, or any regulatable and functional
derivative thereof, and a foreign functional DNA sequence
operatively linked to such region; and to the method of
preparing such host which comprises transforming an
appropriate host microorganism with such vector.

15 Appropriate host microorganisms which may be employed
include viruses or prokaryotic or eukaryotic cells or
organisms, especially actinomycetes such as those of the
genus Streptomyces. The most preferred host
microorganisms belong to the genus Streptomyces.

20 Preferred species of Streptomyces include Streptomyces
lividans, S. coelicolor, S. azureus and S. albus.

Transformation of such host microorganism with such vector
can be accomplished using conventional techniques such as
the method of Chater et al., Curr. Top. Micro. Imm., 96,
25 69-95 (1982). This invention also relates to a method of
expressing the foreign functional DNA sequence contained
by such transformed host of this invention which comprises
cultivating such transformed host under suitable
conditions such that the functional DNA sequence is
30 expressed. By "suitable conditions" is meant those
conditions which will allow the host to grow and which
enable the expression of the functional DNA sequence.

Such suitable conditions can be determined by one of skill
in the art using conventional techniques and will depend
35 on various factors, such as the host organism employed and

1 the foreign functional DNA sequence to be expressed. This
invention also relates to a method of regulating the
expression of the functional DNA sequence contained by
such transformed host which comprises cultivating a
5 transformed host containing such foreign functional DNA
sequence under appropriate conditions such that its
expression is regulatable. By "appropriate conditions" is
meant those conditions which enable the gal operon P1
promoter (and thus the functional DNA sequence) to be
10 regulatable. By "regulatable" is meant responsive to the
presence or absence of galactose or its metabolites and
the presence of glucose or its metabolites in the growth
media of the transformed host cell. Such regulation can
be carried out by addition or deletion of galactose or
15 glucose to the transformed host's culture medium.

EXAMPLES

In the following Examples, specific embodiments
of the invention are more fully disclosed. These Examples
are intended to be illustrative of the subject invention
20 and should not be construed as limiting its scope. In all
Examples, temperature is in degrees Centigrade (°C).

By utilizing conventional methods, such as those
outlined in the following Examples, one of skill in the
art can isolate the gal operon from any galactose
25 utilizing strain of Streptomyces. Furthermore, by
utilizing techniques similar to those employed herein to
isolate the Streptomyces gal operon, one of skill in the
art can attempt to use the Streptomyces gal operon to
isolate a gal operon from other galactose utilizing other
30 strains of Streptomyces, especially S. coelicolor, S.
azuraeus, S. albus and other S. lividans strains.

Molecular genetic manipulations and other
techniques employed in the following Examples are
described in Hopwood et al., Genetic Manipulation of
35 Streptomyces: A Laboratory Manual, John Innes Foundation,
Norwich, England (1985).

1

ABBREVIATIONS

In the following Examples, the following abbreviations may be employed:

5

NaCl

MBSM (modified MBSM): See, Brawner et al., Gene, 40, 191 (1985) (in press)

10

MOPS: (3)-N-morpholino-(propane-sulfonic acid)

YEME + MgCl_2 + Glycine: [per liter(l)] 3 g yeast extract, 5 g peptone, 3 g malt extract, 10 g glucose, 10 g $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$, 340 g sucrose.

15

SL: Mix together $(\text{NH}_4)_2\text{SO}_4$ (1g/l); L-asparagine (2 g/l); K_2HPO_4 (9 g/l); NaH_2PO_4 (1 g/l) for 0.2% agar and autoclave. Then mix with yeast extract (20 g/l), MgCl_2 (5 g/l); CuCl_2 (0.1 g/l); Trace elements [20 ml/l - include ZnCl_2 -40 mg/l; $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$ (200 mg/l); $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$ (10 mg/l); $\text{NaB}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$ (10 mg/l); $(\text{NH}_4)_6\text{MO}_7\text{O}_{24} \cdot 4\text{H}_2\text{O}$ (10 mg/l)] filter and sterilize.

20

YEME (Ym base): (per liter) yeast extract (3g); peptone (5g); malt extract (3g); $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$ (2g)

25

Ymglu: YEME + glucose (10g)

Ymgal: YEME + galactose (10g)

30

35

1

BACTERIAL STRAINS

In the following Examples, the following strains of E. coli are employed:

5

	CGSC Strain #(a)	Strain Designation	Sex	Chromosomal Markers
	4473 (<u>galE</u> ⁻)	W3109	F ⁻	<u>galE9</u> , ^(b) g ⁻ ;IN(rrnD-rrnE)1
	4467 (<u>galT</u> ⁻)	W3101	F ⁻	<u>galT22</u> ^(b) g ⁻ ;IN(rrnD-rrnE)1
10	4498 (<u>galE</u> ⁻)	PL-2	Hfr	<u>thi-1</u> , <u>relA1</u> , <u>921E28</u> ,g ⁻ , <u>spoT1</u>

(a) CGSC Strain # is the stock number designated for such strain by the E. coli Genetic Stock Center of the Department of Human Genetics, Yale University School of Medicine, 333 Cedar Street, P.O. Box 3333, New Haven, Connecticut, 06510, U.S.A.

(b) galE9 is the old Lederberg gal9; galT22 is the old Lederberg gal₁.

20

S1 ANALYSIS

S1 analysis is used to identify the 5' end of RNAs and the length of a RNA of interest. In the following Examples, S1 analysis refers to S1 experiments carried out according to the method of Weaver et al., Nucl. Acids Res., 7, 1175 (1979) and Berk et al., Proc. Natl. Acad. Sci. USA, 75, 1214 (1978).

25

EXAMPLE I

A. CLONING OF A STREPTOMYCES LIVIDANS GALACTOKINASE GENE.

30

Streptomyces lividans strain 1326 is described by Bibb et al., Mol. Gen. Genetics, 184, 230-240 (1981) and was obtained from D. A. Hopwood, John Innes Foundation, Norwich, England. Streptomyces lividans strain 1326 and S. lividans strain 1326 containing the pIJ6 plasmid were deposited in the Agricultural Research Culture Collection,

35

1 Peoria, Illinois, U.S.A., on June 1, 1982, under accession numbers NRRL 15091 and 15092, respectively.

5 High molecular weight chromosomal DNA was isolated from Streptomyces lividans strain 1326 according to the method of Maniatis et al., "Molecular Cloning. A Laboratory Manual", Cold Spring Harbor Laboratory (1982) and was size fractionated on a 10-40% sucrose gradient (See, Maniatis et al., cited above, p. 284-285).

10 Fractions of 18-24 kilobase (Kb) pairs were combined and dialyzed exhaustively against 10 mM Tris-HCl/1 mM EDTA (pH 8). Cosmid shuttle vector pJW357 was employed to clone such fractionated chromosomal DNA in its entirety. pJW357 was constructed by fusing pDPT6 cut with PstI to pIJ350 cut with PstI. pIJ350 is described in Kieser et al., Mol. Gen. Genet., 185, 223-238 (1982). pDPT6 is a tetracycline and chloramphenicol resistant, pBR322-based E. coli cosmid cloning vector described in Taylor et al., U.S. Patent No. 4,476,227. pJW357 has a unique EcoRI site in the
20 chloramphenicol resistance gene and a unique BamHI site in the Tc^R (tetracycline) resistance gene. pJW357 was digested with BamHI, dephosphorylated with alkaline phosphatase, and ligated to the fractionated chromosomal DNA described above.

25 The ligation product was packaged into bacteriophage heads (using the in vitro packaging system described by Maniatis et al., cited above, p. 264-265) and transfected into E. coli strain K21 which is a galK⁻ derivative of E. coli MM294. The transformation culture was grown for two hours in LB and for an additional two
30 hours in LB with 25 ug/ml chloramphenicol, washed three times with equal volumes of M9 media [see, Miller, "Experiments in Molecular Genetics", Cold Spring Harbor Laboratory (1972)] without a carbon source, and plated
35 onto M9 agar [supplemented with proline, histidine, arginine, isoleucine, leucine, saline and .5% galactose;

1 See, Adams et al., Biochem. Biophys. Res. Comm., 89(2),
650-58 (1979)] with 30 mg/ml chloramphenicol. Twenty
plates were spread with approximately 200 transformants
per plate. After three days incubation at 37°C, no
5 transformants were detected. The minimal plates were then
sprayed with nicotinic acid to 5 ug/ml to supplement the
nicotinic acid requirement of E. coli strain K21, and the
incubation was continued for 3 more days at 37°C and for 2
additional days at room temperature. After such
10 incubation, the surviving colonies were patched to both
MacConkey galactose agar (MAC-GAL) [See, Miller et al.,
cited above] with 30 ug/ml chloramphenicol and to M63
minimal agar [See, Miller et al., cited above]
supplemented with .5% galactose, 5 ug/ml nicotinic acid, 5
15 ug/ml thiamine and 30 ug/ml chloramphenicol. Only two
colonies contained cosmid DNA that transformed E. coli K21
to a galK⁺ phenotype. Such cosmids were designated as
pSLIVGAL-1 and pSLIVGAL-2. Both colonies were light red
on MAC-GAL (i.e., they were galK⁺) and also grew on the
20 M63 medium.

Plasmids pSLIVGAL-1 and pSLIVGAL-2 were isolated
from the two galK⁺ colonies described above and were
transformed, according to the method of Chater et al.,
Curr. Top. Micro. Imm., 96, 69-95 (1982), into Streptomyces
25 lividans strain 1326-12K (a galK deficient strain isolated
after UV mutagenesis of S. lividans strain 1326, See,
Brawner et al., Gene, 40, 191 (1985), (in press). Plasmid
encoded complementation of the S. lividans 1326-12K
(galK⁻) host was tested by observing growth of spores
30 plated on MBSM-gal-thiostrepton according to the method of
Brawner et al., Gene, 40, 191 (1985) (in press).
pSLIVGAL-2 showed no detectable complementation of the
Streptomyces 1326-12K host.

Cell extracts were prepared from cultures grown
35 in SL medium supplemented with 1% glucose or galactose and
10 %g/ml thiostrepton. The extracts were analyzed for

1 galactokinase production by immunoblot analysis (see,
Brawner et al., Gene, 40, 191 (1985), in press) using
rabbit antisera prepared against E. coli galactokinase.
5 The protein detected by immunoblot analysis was the
approximate size of E. coli galK. Such protein appeared
in galactose supplemented cultures of Streptomyces at
levels several fold higher than in glucose cultures.

10 B. MAPPING OF THE S. LIVIDANS GALK REGION WITHIN A COSMID.

The galK region of the pSLIVGAL1 and pSLIVGAL2
cosmids, prepared as described above, was identified by
cloning random fragments from the cosmids into a pUC18
derivative [See, Norrander et al., Gene, 26, 101-106
15 (1983)] and scoring complementation of E. coli strain
MM294 (galK⁻) on MAC-GAL medium. The cosmid clone was
partially digested with Sau3AI (using conditions which
maximized the yield of 2 to 4 kilobase fragments), and the
products of this reaction were ligated into the BglII site
20 of pUC18-TT6, a derivative of pUC18 constructed by
insertion of the following synthetic DNA sequence into the
BamHI site of pUC18:

5'GATCAGATCTTGATCACTAGCTAGCTAG 3'
3' TCTAGAACTAGTGATCGATCGATCCTAG 5'

25

Twelve galK⁺ clones (red on MAC-GAL) were screened for
size. One clone, designated as plasmid pSAU10, was the
smallest and had an insert size of approximately 1.4 Kb.

30 In contrast to colonies containing pSLIVGAL1, the
pUC clones were very red on MAC-GAL medium, indicating an
increased production of galactokinase. The most likely
explanation for the increased enzyme level was that the S.
lividans galK gene was now being transcribed by an E. coli
35 promoter which was stronger than the upstream promoter on
the cosmid.

1

The insert of pSAU10 was isolated as an EcoRI to HindIII fragment (these sites flank the insert region of pUC18-TT6) for use as a probe for the S. lividans galK gene. The chromosomal DNA used in the cloning was restricted with EcoRI plus MluI and BamHI plus BglII, and then blotted according to the method of Southern, J. Mol. Biol., 98, 503 (1975). The pSAU10 fragment was nick translated and hybridized to the blot. The probe identified a 1.3 kb EcoRI-MluI fragment and a 5 kb BamHI-BglII fragment in the chromosomal digests. When this data was compared to the map of the cosmid insert, the location of the galK gene (between map positions 5 and 7, See Table A) was confirmed.

15

C. DNA SEQUENCING OF THE S. LIVIDANS GAL OPERON.

The Streptomyces lividans gal operon was sequenced by chain termination [(See, Sanger et al., Proc. Nat'l Acad. Sci., U.S.A., 74, 5463 (1977))] and chemical cleavage [See, Maxam and Gilbert, Methods in Enzymology, 65, 499 (1980)]. The initial sequences of galK were derived from Sau3AI and SalI fragments of the insert of pSAU6 (a 2.3 Kb sibling of pSAU10) shotgun cloned into the BamHI and SalI sites (respectively) of M13 mp 10 [See, Messing, Methods in Enzymology, 101, 20 (1983)]. Amino acid sequences of the S. lividans galT, galE and galK genes were predicted by computer, and further analyzed by comparison with amino acid sequences of the E. coli and or S. cerevisiae galactokinase, gal-1-phosphate uridylyltransferase and UDP-4-epimerase enzymes. The sequences of these proteins were predicted by computer analysis using the total or partial DNA sequence of the genes which encode the gal enzymes [see, Debouck et al., Nuc Acids. Res., 13(6), 1841-1853 (1985), and Citron and Donelson, J. Bacteriology, 158, 269 (1984)]. Some homology was found between the inferred protein sequence

35

1

for the S. lividans galK, galT, galE gene products and their respective E. coli and/or S. cerevisia gene products.

5

The complete DNA sequence of the S. lividans gal operon is shown in Table 1. Included in Table 1 are the transcription start sites for the operon's promoters and the predicted amino acid sequences of the galT, galE and galK gene products.

EXAMPLE 2PROMOTERS OF THE S. LIVIDANS GAL OPERON

a) P1 promoter

(i) Summary

5

10

This promoter is galactose inducible, glucose repressible and is the regulatable promoter for the entire Streptomyces gal operon. S1 data indicates that the Streptomyces lividans gal operon encodes a polycistronic transcript of approximately 3.4 kilobases (Kb). The transcript consists of approximately 1 Kb for galT, followed by approximately 1 Kb each for galE and galK. (See, Figure 1).

15

Galactose induction of P1 is mediated, at least in part, by an operator sequence whose 5' end is located 31 bp upstream of the transcription start site and a repressor protein which recognizes the operator.

(ii) Experimental: Isolation, Localization, and Characterization of the P1 promoter.

20

25

30

35

The sequences upstream of the Streptomyces lividans galK ATG were screened for promoters using the E. coli galK promoter probe system of Brawner, et al., Gene, 40, 191, (1985), in press. The HindIII-MluI fragment (See, Table A, map positions 1-5) was restricted with Sau3AI, ligated into the unique BamHI site of pK21 (Figure 2), and transformed into E. coli K21 (galK⁻) according to the method of Example 1. pK21 is a derivative of pSKO3 and is an E. coli-Streptomyces shuttle vector containing the E. coli galK gene (See, Figure 2). The construction of pSKO3 is described in Rosenberg et al., Genetic Engineering, 8, (1986), in press. The clones which expressed galK, i.e., those which had promoter activity, were identified on MacConkey - galactose plates. Two galK⁺ clones (designated as pK21 MH1 and 2) were transformed into Streptomyces 1326-12K (galK⁻).

1

Extracts from transformants were cultured in Ymglu and Ymgal, and were analyzed by western blot analysis using anti-E. coli galactokinase antiserum. The blots showed significantly higher levels of galactokinase in the extracts from the galactose induced cultures.

5

pK21 MH1 and 2 were shown by restriction analysis to contain a 410 bp Sau3AI insert which is contained within the HindIII and BglII sites (see Table A, map positions 1-2) by Southern blot analysis according to the method of Southern, J. Mol. Biol., 98, 503 (1975). The cloned fragment was analyzed by S1 analysis using RNA isolated from Streptomyces lividans 1326-12K and E. coli K21 cultures. The fragment yielded a 290 nucleotide protected fragment after S1 digestion (indicating the 5' end of an mRNA 290 bp upstream of the Sau3AI site). Hybridization experiments (using single stranded M13 clones of this region) have identified the direction of transcription as left to right as shown in Figure 2 (i.e., transcription is going toward galK).

10

15

20

Conventional DNA sequence analysis and additional S1 mapping analysis were used to define the 5' end of the mRNA.

25

30

The sequences responsible for regulating galactose induction of P1 were localized by removing sequences upstream of the transcription start site by nuclease Bal31. Any change in promoter function or galactose induction by removal of these sequences was assessed using the E. coli galK promoter probe plasmid used to identify P1.

(iii) Construction of Gal Promoter Deletions.

35

Plasmid pHL5 was constructed by cloning a DNA fragment containing 100 bp of sequences downstream from the start of P1 transcription and 216 bp upstream from the start of P1 transcription into plasmid pUC19TT1. Plasmid pUC19TT1 is described in Norrander et al., Gene, 26, 101-106 (1983) and has the Unker as pUC18-TT6. See, Example IB. Deletions extending into the upstream

1 sequence preceeding P1 were generated by linearizing pHL5
with HindIII and treating the ends with nuclease Bal31.
The uneven ends were subsequently repaired with the Klenow
fragment of DNA polymerase I. Bal31-treated pHL5 was then
5 digested with BamHI and run on a 5% acrylamide gel. DNA
fragments in the molecular weight range of 100-300 bp were
eluted from the gel and subcloned into M13 mp 10 that had
been digested with HindII and BamHI. [See, Messing,
Methods in Enzymology, 101, 20 (1983)]. Individual
10 deletions were then sequenced from the single stranded
phage DNA the dideoxy chain termination method of Sanger,
et al., cited above.

(iv) Linking the P1 Promoter Deletions to the
E. coli galK Gene.

15 The various mp 10 clones were digested with BamHI
and HindIII. DNA fragments containing individual
deletions were isolated from low-melting point agarose
gels and then ligated to pK21 (see, Figure 2) that had
been digested with BamHI and HindIII. After
20 transformation into E. coli MM294, plasmid DNA was
isolated for each of the deletion derivatives and
transformed into Streptomyces lividans 12K.

(v) Functional Assessment of Bal
31-Generated Deletions in S. lividans

25 For each individual promoter deletion, a single
thiostrepton resistant transformant was grown to late log
in YM base (YEME) + 10 ug/ml thiostrepton. Cells were
then pelleted, washed once in M56 media and resuspended in
M56 media (see Miller, et al., cited above). The washed
30 cells were then used to inoculate YM + 0.1M MOPS (pH 7.2)
+ 10 ug/ml thiostrepton supplemented with 1% galactose or
1% glucose. The cells were grown for 16 hours then
assayed for galactokinase activity.

Ten individual pK21 derivatives containing either
35 120, 67, 55, 34, 31, 24, 20, 18, 10 or 8 bp of sequence
upstream of the P1 transcription start site were analyzed

1

for galactokinase expression. These results showed that all the information necessary for galactose induction of P1, (i.e., 10-20 fold greater levels of galactokinase produced in galactose grown cells versus glucose grown cells) is included in the 31 bp of sequence upstream of P1. A deletion which leaves 34 bp of sequence upstream of P1 is partially inducible by galactose since galactose induced 6-fold greater amounts of galactokinase. Thus, one end of the operator must be situated within the sequences between the -24 and -31 position. The remaining deletions which leave either 20, 18, 10 or 8 bp of upstream sequence result in a constitutive P1 promoter, that is the levels of galactokinase produced were equivalent when cells were grown in the presence of galactose or glucose. Although the promoter deletions which retained 8 and 10 bp of P1 were constitutive, the amount of galactokinase produced was reduced 10 fold in comparison to the promoter deletions which retained 18 to 120 bp of upstream sequence. This result indicates that sequences between the -10 and -18 positions of -1 are essential for promoter function.

This data supports a model in which galactose induction of P1 is mediated, at least in part, by an operator sequence. One end of this sequence is 24 to 31 bp upstream of the P1 transcription start site. Removing part or all of the operator results in a promoter which is partially or totally derepressed. The other end of this sequence has not been defined by these experiments but it most likely is contained within the 24 to 31 bp of sequence upstream of the P1 transcription start site. In addition we cannot eliminate the possibility that the 3' end of the operator is also within the 100 bp downstream of the transcription start site since these sequences were contained within the smallest region needed to achieve galactose induction. These data also suggest that the factor which interacts with the operator sequence is a

1

repressor protein. Finally, we do not have any evidence which eliminates the possibility that P1 may be controlled by factors other than a repressor (i.e., positive
5 activator such as lambda phage cII protein) to modulate galactose induction promoter transcript.

b) P2 promoter

(i) Summary

10 The P2 promoter of the Streptomyces gal operon is upstream of the galE gene and transcribes both galE and galK genes.

P2 promoter expression is constitutive (i.e., not glucose repressed/galactose induced) as shown by S1 analysis.

15 (ii) Experimental: Isolation, Localization, and Characterization of the P2 promoter.

The existence of the Streptomyces gal operon P2 promoter became apparent when the BglII-MluI fragment (see, Table A, map positions 2-5) of S. lividans 1326 DNA
20 was inserted into plasmid pK21 (see, Figure 2) and galactokinase expression was observed in Streptomyces lividans 1326-12K transformed therewith.

DNA sequence analysis and S1 analysis were used to identify the 5' end of the S. lividans gal operon P2.
25 The 5' end of the P2 promoter transcript is within 100 bp upstream of the predicted galE ATG.

EXAMPLE 3

EVIDENCE OF A POLYCISTRONIC MESSAGE IN THE
STREPTOMYCES GAL OPERON

30

S1 analysis was used to map the transcripts upstream and downstream of the Streptomyces lividans gal operon galK gene. In general, overlapping DNA fragments of 1-2 Kb were isolated from subclones, further
35 restricted, and end labelled. The message was followed from the 3' end of galK to the upstream end at P1.

1

The 3' end of the Streptomyces lividans gal operon transcript probably occurs within the first hundred bases downstream of galK. Fragments 3' labelled at sites
5 within the galK sequence were not protected to their full length (S1 analysis) if they extend into this downstream region. One experiment showed a possible protected region that terminated 50-100 bp downstream of the galK translation stop. The existence of a transcription
10 terminator can be confirmed by conventional techniques by using a terminator probe system. The gal operon transcript clearly does not extend to the PvuII site (see, Table A, map position 8) because no full length protection of 5' labelled PvuII fragments occurs from that site.

15 5' end labelled fragments from two PvuII fragments, fragment I, (map positions 4-6, See, Table A), and fragment II, (map positions 6-8, See Table A), and the insert of pSaul0 were used as sources of probes for S1 walking from the 3' to 5' end of the message. All
20 fragments through this region are protected, except the fragment containing the P2 promoter which shows partial and full protection. The complete protection from S1 digest indicates a polycistronic message which initiates upstream at P1 and continues to approximately 100 bp
25 downstream of galK.

The above data is indirect evidence of a polycistronic mRNA of the Streptomyces gal operon. S1 analysis using a long contiguous DNA fragment (e.g., the 4.5 kb HindIII-SacI fragment, see map position 7 of Table
30 A) has been used to confirm the transcript size.

35

1

EXAMPLE 4

LOCALIZATION OF S. LIVIDANS GAL OPERON GALE AND GALT GENES

5 (i) Summary

The S. lividans gal operon galE gene was localized to 1.5 Kb PvuII fragment (map position, 4-6 of Table A) of pLIVGAL1 (Figure 1).

10 The S. lividans gal operon galE coding sequences extend through the MluI site (map position 5 of Table A).

The S. lividans gal operon galT gene was localized within the 1.15 Kb Nru-PvuII region (see, Table A, map positions 1a-4) of pSLIVGAL1.

15 The direction of S. lividans gal operon galE and galT transcription is the same as galK gene.

(ii) Experimental

It was necessary to identify the other functions contained on pLIVGAL1; specifically, does this plasmid encode for the enzyme galactose epimerase (galE) or the enzyme galactose transferase (galT). The Streptomyces gal operon galK gene was identified by its ability to complement an E. coli galK host. Thus, identification of the Streptomyces galT and galE genes was tested for by complementation of E. coli galE⁻ or galT⁻ hosts, respectively. An E. coli galT⁻ strain (CGSC strain #4467, W3101) and two galE⁻ strains (CGSC strain #4473; W3109 and CGSC strain #4498; PL-2) were obtained to test for complementation by the pSLIVGAL1 clone.

30 The ca. 9 Kb HindIII-SphI fragment (see, Table A, map positions 1-16) containing the Streptomyces lividans gal operon galK gene was inserted into pUC19. This fragment was situated within pUC19 such that transcription from the Plac promoter of pUC19 is in the same direction as the Streptomyces galK gene. pUC19 is described in Yanisch-Perrou, et al., Gene, 33, 103 (1983).

35 Complementation was assayed by growth on MacConkey-galactose plates. Cells which can utilize galactose

1

[galE⁺, galT⁺, galK⁺] will be red to pink on this medium. E. coli strain PL-2 (see, Example 2) containing pUC19 with the HindIII-SphI insert were pink on the indicator plate indicating that the HindIII-SphI fragment contains the Streptomyces lividans galE gene. The galE gene was later mapped to within the 4.5 Kb HindIII-SacI (the SacI site is near the region around map position 7-8 of Table A) fragment. If the sequences from the MluI site (map position 5 of Table A) to the SacI site were removed galE complementation of E. coli PL-2 was not detected. The 5' end of the galK gene is 70 base pairs (bp) from the MluI site. Therefore it seemed likely that the MluI site was contained within the 5' or 3' end of the galE gene.

5

10

15

20

25

30

To determine the direction of galE transcription, the HindIII-SacI fragment was inserted into pUC18. In this configuration, the Streptomyces lividans galK gene is in the opposite orientation with respect to Plac. The pUC18 HindIII-SphI clone did not complement E. coli PL-2 indicating the galE is transcribed in the same direction as galK. In addition it was concluded that the MluI site is contained within the 3' end of the galE gene. DNA sequence analysis of the PvuII-MluI fragment (See, Table A, map position 4-5) has identified an open reading frame which encodes for a polypeptide of predicted molecular weight of 33,000 daltons. The 5' end of this reading frame is located approximately 176 bp from the PvuII site (See, Table A, map position 4). Therefore, the sequencing results support the conclusion that the 3' end of galE traverses the MluI site (see, Table A, map position 5).

Similar experiments to localize the galT gene on pSLIVGAL1 were attempted with the galT hosts.

The region between P1 and the 5' end of galE was sequenced to identify the galT gene. Translation of the DNA sequence to the amino acid sequence identified a reading frame which encodes a protein showing a region of homology to the yeast transferase.

1

EXAMPLE 5

GALACTOSE INDUCTION OF S. LIVIDANS GAL OPERON GALK GENE

5

(i) Summary

Galactokinase expression is induced within one hour after the addition of galactose to culture medium.

10 Galactokinase expression is 10 times higher in the presence of galactose versus glucose or no additional carbon source within 6 hours after addition of the sugar.

(ii) Experimental

15 Galactose induction of the Streptomyces lividans galK gene was examined by assaying for galactokinase activity at 1, 3, 6 and 24 hours after the addition of galactose. Two liters of YM + 0.1M MOPS (pH 7.2) were inoculated with 2×10^7 spores of Streptomyces lividans 1326. After 21 hours growth, galactose or glucose were added to a final concentration of 1%. One, three, six and
20 twenty four hours after the addition of sugar, cells were isolated and assayed for galactokinase activity. Total RNA was prepared by procedures described in Hopwood et al., cited above.

25 An increase in galactokinase synthesis was observed one hour after the addition of galactose. The increase continued over time (1 to 24 hours). S1 analysis of RNA isolated from the induced cultures confirmed that the increase in galK activity was due to increased levels of the P1 promoter transcript.

30 The S1 data and the induction studies suggest the following model for gene expression within the Streptomyces gal operon. The P1 promoter is the galactose inducible promoter. The P1 transcript includes galT, galE and galK. The P2 promoter is constitutive and its
35 transcript includes galE and galK.

1

It is interesting to note that the E. coli gal operon also has two promoters, P1 and P2. [See, Nusso et al., Cell, 12, 847 (1977)]. P1 is activated by cAMP-CRP binding whereas P2 is inhibited by cAMP-CRP. Translation of the E. coli gal operon galE coding sequence is more efficient when transcription initiates at P2 which serves to supply a constant source of epimerase even in the absence of galactose or the presence of glucose [See, Queen et al., Cell, 25, 241 (1981)]. The epimerase functions to convert galactose to glucose 1-phosphate during galactose utilization and convert UDP-glucose to UDP-galactose which is required for E. coli cell wall biosynthesis. It is possible that the P2 promoter of the Streptomyces galK operon also serves to supply epimerase and galactokinase in the absence of galactose or during secondary metabolism.

20

EXAMPLE 6
THE S. COELICOLOR GAL OPERON

(i) Summary

The restriction map of a fragment containing the S. coelicolor galK gene is identical to the restriction map of the S. lividans gal operon. (See, Figure 3).

S. coelicolor can grow on minimal media containing galactose as the sole carbon source.

Galactokinase expression in S. coelicolor is induced by the addition of galactose to the growth media.

A promoter analogous and most likely identical to P1 is responsible for galactose induction of the S. coelicolor gal operon.

(ii) Experimental

An approximately 14 kb partial Sau3A fragment containing the S. coelicolor galK gene was isolated by K. Kendall and J. Cullum at the University of Manchester Institute of Science and Technology, Manchester, UK

1 (unpublished data; personal communication). They were
able to localize the S. coelicolor galK gene within a 3 kb
EcoRI fragment by complementation of a S. coelicolor galK
mutant. The position of a number of restriction sites
5 within the S. lividans gal operon are identical to those
found within, upstream and downstream of the EcoRI
fragment containing the S. coelicolor galK gene
(Figure 3). Thus, it seems likely that the gene
organization of the S. coelicolor gal operon is identical
10 to the S. lividans gal operon.

Galactose induction of the S. coelicolor galK
gene was examined by immunoblotting. S. coelicolor was
grown in YM + 1% galactose or 1% glucose (Ymglu or Ymgal)
for 20 hours at 28 C. Galactokinase expression was
15 detected using rabbit antisera prepared against purified
E. coli galactokinase. The protein detected was the
approximate size of the E. coli and S. lividans galK gene
product. Galactokinase expression is galactose induced
since it was detected only when S. coelicolor was grown in
20 Ym + galactose (Ymgal).

S1 nuclease protection studies were performed to
determine if galactose induction of the S. coelicolor gal
operon is directed by a promoter analogous to the S.
lividans P1 promoter. RNA was isolated from S. coelicolor
25 grown in Ym + 1% galactose or 1% glucose (Ymgal or
Ymglu). The hybridization probe used for S1 analysis of
this RNA was a 410 bp Sau3A fragment which contains the S.
lividans P1 promoter, its transcription start site and the
5' end of the galT gene. The S1 protected fragment
30 detected by this analysis co-migrated with the protected
fragment detected when the probe was hybridized to RNA
isolated from S. lividans grown in the presence of
galactose. Thus, this result shows that galactose
induction of the S. coelicolor gal operon is directed by a
35 sequence indistinguishable from the S. lividans P1
promoter.

1

It should be noted that the following strains of Streptomyces have been observed to be able to grow on medium containing galactose as the only carbon source:

5

S. albus J1074 (obtained from Dr. Chater, John Innes Foundation, Norwich, England)

S. carzinostaticus - ATCC accession number 15944

S. carzinostaticus - ATCC accession number 15945

10 S. antifibrinolyticus - ATCC accession number 21869

S. antifibrinolyticus - ATCC accession number 21870

S. antifibrinolyticus - ATCC accession number 21871

S. longisporus - ATCC accession number 23931

15

The abbreviation "ATCC" stands for the American Type Culture Collection, Rockville, Maryland, U.S.A.

20 While the above descriptions and Examples fully describe the invention and the preferred embodiments thereof, it is understood that the invention is not limited to the particular disclosed embodiments. Thus, the invention includes all embodiments coming within the scope of the following claims.

25

30

35

1

Claims for the Contracting States :
BE, CH, DE, FR, GB, IT, LI, LU, NL, SE

5

1. A recombinant DNA molecule comprising a Streptomyces gal operon or any regulatable and functional derivative thereof.

10

2. The molecule of Claim 1 wherein the operon is a S. lividans, S. coelicolor, S. azuraeus, S. albus, S. carzinostaticus, S. antifibrinolyticus or S. longisporus gal operon.

15

3. The molecule of Claim 2 wherein the operon is a S. lividans gal operon.

4. The molecule of Claim 3 which has the following coding sequence:

comprises a foreign functional DNA sequence operatively
linked to such operon.
- 5 6. A transformed host microorganism or cell
comprising the molecule of Claim 5.
7. A method of preparing a transformed host
microorganism or cell comprising the molecule of Claim 5
which comprises transforming an appropriate host
microorganism or cell with such molecule.
- 10 8. A recombinant DNA vector comprising the
molecule of Claim 5, and, optionally, additionally
comprising a replicon.
9. A transformed host microorganism or cell
comprising the recombinant DNA vector of Claim 8.
- 15 10. A method of preparing a transformed host
microorganism or cell comprising the recombinant DNA
vector of Claim 8 which comprises transforming an
appropriate host microorganism or cell with such vector.
11. A method of expressing a foreign functional
20 DNA sequence which comprises cultivating a transformed
host microorganism or cell comprising the recombinant DNA
vector of Claim 8 under suitable conditions such that the
functional DNA sequence is expressed.
12. A method of regulating the expression of a
25 foreign functional DNA sequence which comprises
cultivating a transformed host microorganism or cell which
contains the recombinant DNA vector of Claim 8 under
appropriate conditions such that expression of the
sequence is regulatable.
- 30 13. A recombinant DNA molecule comprising a
Streptomyces gal operon P2 promoter expression unit or any
functional derivative thereof.
14. The molecule of Claim 13 wherein the
expression unit is a S. lividans, S. coelicolor, S.
35 azuraeus, S. albus, S. carzinostaticus, S.
antifibrinolyticus or S. longisporus gal operon P2
promoter expression unit.

i

1. The molecule of Claim 14 which is a S. lividans gal operon P2 promoter expression unit.

5

16. The molecule of Claim 13 which further comprises a foreign functional DNA sequence operatively linked to such expression unit.

17. A transformed host microorganism or cell comprising a recombinant DNA molecule wherein such molecule comprises the molecule of Claim 16.

10

18. A method of preparing a transformed host microorganism comprising the molecule of Claim 16 which comprises transforming an appropriate host microorganism or cell with such molecule.

15

19. A recombinant DNA vector comprising the molecule of Claim 16, and, optionally, additionally comprising a replicon.

20. A transformed host microorganism or cell comprising the recombinant DNA vector of Claim 19.

20

21. A method of preparing a transformed host microorganism or cell comprising the recombinant DNA vector of Claim 19 which comprises transforming an appropriate host microorganism with such vector.

25

22. A method of expressing a foreign functional DNA sequence which comprises cultivating a transformed host microorganism or cell comprising the recombinant DNA vector of Claim 19 under suitable conditions such that the functional DNA sequence is expressed.

23. A recombinant DNA molecule comprising a Streptomyces gal operon P1 promoter regulated region or any regulatable and functional derivative thereof.

30

24. The molecule of Claim 23 wherein the region is a S. lividans, S. coelicolor, S. azuraeus, S. albus, S. carzinostaticus, S. antifibrinolyticus or S. longisporus gal operon P1 promoter regulated region.

35

25. The molecule of Claim 24 wherein the region is a S. lividans gal operon P1 promoter regulated region.

1 26. The molecule of Claim 23 which further
comprises a foreign functional DNA sequence operatively
linked to such regulated region.

5 27. A transformed host microorganism or cell
comprising the molecule of Claim 26.

 28. A method of preparing a transformed host
microorganism or cell comprising the molecule of Claim 26
which comprises transforming an appropriate host
microorganism or cell with such molecule.

10 29. A recombinant DNA vector comprising the
molecule Claim 26, and, optionally, additionally
comprising a replicon.

 30. A transformed host microorganism or cell
comprising a recombinant DNA vector of Claim 29.

15 31. A method of preparing a transformed host
microorganism or cell comprising the recombinant DNA
vector of Claim 29 which comprises transforming an
appropriate host microorganism or cell with such vector.

 32. A method of expressing a foreign functional
20 DNA sequence which comprises cultivating a transformed
host microorganism or cell comprising the recombinant DNA
vector of Claim 29 under suitable conditions such that the
functional DNA sequence is expressed.

 33. A method of regulating the expression of a
25 foreign functional DNA sequence which comprises
cultivating a transformed host microorganism or cell which
contains the recombinant DNA vector of Claim 29 under
appropriate conditions such that expression of the
sequence is regulatable.

30 34. A recombinant DNA molecule comprising a
Streptomyces gal operon P2 promoter or any functional
derivative thereof.

 35. The molecule of Claim 34 wherein the promoter
is a S. lividans, S. coelicolor, S. azuraeus, S. albus, S.
35 carzinostaticus, S. antifibrinolyticus or S. longisporus
gal operon P2 promoter.

1

36. The molecule of Claim 35 wherein the promoter is a S. lividans gal operon P2 promoter.

5

37. The molecule of Claim 34 which further comprises a foreign functional DNA sequence operatively linked to the P2 promoter.

38. A transformed host microorganism or cell comprising the molecule of Claim 37.

10

39. A method of preparing a transformed host microorganism or cell comprising the molecule of Claim 37 which comprises transforming an appropriate host microorganism or cell with such molecule.

40. A recombinant DNA vector comprising the molecule of Claim 37 and, optionally, additionally comprising a replicon.

15

41. A transformed host microorganism or cell comprising the recombinant DNA vector of Claim 40.

20

42. A method of preparing a transformed host microorganism or cell comprising the recombinant DNA vector of Claim 40 which comprises transforming an appropriate host microorganism with such vector.

25

43. A method of expressing a foreign functional DNA sequence which comprises cultivating a transformed host microorganism or cell comprising the recombinant DNA vector of Claim 40 under suitable conditions such that the functional DNA sequence is expressed.

44. A recombinant DNA molecule comprising a Streptomyces gal operon P1 promoter or any regulatable and functional derivative thereof.

30

45. The molecule of Claim 44 wherein the promoter is a S. lividans, S. coelicolor, S. azureus, S. albus, S. carzinostaticus, S. antifibrinolyticus or S. longisporus gal operon P1 promoter.

46. The molecule of Claim 45 wherein the promoter is a S. lividans gal operon P1 promoter.

35

47. The molecule of Claim 44 which further comprises a foreign functional DNA sequence operatively linked to the P1 promoter.

1 48. A transformed host microorganism or cell
comprising the molecule of Claim 47.

5 49. A method of preparing a transformed host
microorganism or cell comprising molecule of Claim 47
which comprises transforming an appropriate host
microorganism or cell with such molecule.

 50. A recombinant DNA vector comprising the
molecule of Claim 47, and, optionally, additionally
comprising a replicon.

10 51. A transformed host microorganism or cell
comprising the recombinant DNA vector of Claim 50.

 52. A method of preparing a transformed host
microorganism or cell comprising the recombinant DNA
vector of claim 50 which comprises transforming an
15 appropriate host microorganism with such vector.

 53. A method of expressing a foreign functional
DNA sequence which comprises cultivating a transformed
host microorganism or cell comprising the recombinant DNA
vector of Claim 50 under suitable conditions such that the
20 functional DNA sequence is expressed.

 54. A method of regulating the expression of a
foreign functional DNA sequence which comprises
cultivating a transformed host microorganism or cell which
contains the recombinant DNA vector of Claim 50 under
25 appropriate conditions such that expression of the
sequence is regulatable.

 55. A recombinant DNA molecule comprising a
Streptomyces gal operon galE gene, or any functional
derivative thereof.

30 56. The molecule of Claim 55 wherein the gene is
a S. lividans, S. coelicolor, S. azuraeus, S. albus, S.
carzinostaticus, S. antifibrinolyticus or S. longisporus
gal operon galE gene.

35 57. The molecule of Claim 56 wherein the gene is
a S. lividans gal operon galE gene.

1 58. The molecule of Claim 55 which further
comprises a foreign functional DNA sequence operatively
linked to the galE gene.

5 59. A transformed host microorganism or cell
comprising the molecule of Claim 58.

60. A method of preparing a transformed host
microorganism or cell comprising the molecule of Claim 58
which comprises transforming an appropriate host
microorganism or cell with such molecule.

10 61. A recombinant DNA molecule comprising a
Streptomyces gal operon galT gene, or any functional
derivative thereof.

15 62. The molecule of Claim 61 wherein the gene is
a S. lividans, S. coelicolor, S. azureus or S. albus, S.
carzinostaticus, S. antifibrinolyticus and S. longisporus
gal operon galT gene.

63. The molecule of Claim 62 wherein the gene is
a S. lividans gal operon galT gene.

20 64. The molecule of Claim 61 which further
comprises a foreign functional DNA sequence operatively
linked to the galT gene.

65. A transformed host microorganism or cell
comprising the molecule of Claim 64.

25 66. A method of preparing a transformed host
microorganism or cell comprising the molecule of Claim 64
which comprises transforming an appropriate host
microorganism or cell with such molecule.

30 67. A recombinant DNA molecule comprising a
Streptomyces lividans gal operon galK gene, or any
functional derivative thereof.

68. The molecule of Claim 67 wherein the gene is
a S. lividans, S. coelicolor, S. azureus, S. albus, S.
carzinostaticus, S. antifibrinolyticus or S. longisporus
gal operon galK gene.

35 69. The molecule of Claim 68 wherein is a S.
lividans gal operon galK gene.

1 70. The molecule of Claim 67 which further
comprises a foreign functional DNA sequence operatively
linked to the galK gene.

5 71. A transformed host microorganism or cell
comprising the molecule of Claim 70.

72. A method of preparing a transformed host
microorganism or cell comprising the molecule of Claim 70
which comprises transforming an appropriate host
microorganism or cell with such molecule.

10 73. A method of enabling a nongalactose
utilizing host microorganism or cell to utilize galactose
which comprises transforming such host with a recombinant
DNA vector or molecule comprising a Streptomyces gal
operon, or any portion of the Streptomyces gal operon
15 which is adequate to enable such transformed host to
utilize galactose, or any functional derivative thereof.

74. A transformed host prepared by the method of
Claim 73.

which comprises transforming an appropriate host micro-
 organism or cell with such molecule.

35

2. A method of preparing a transformed host microorganism or cell comprising a recombinant DNA vector comprising the sequence of Claim 1 which comprises transforming an appropriate host microorganism or cell
5 with such vector.

3. A method of expressing a foreign functional DNA sequence which comprises cultivating a transformed host microorganism or cell comprising the recombinant DNA vector of Claim 2 under suitable conditions such
10 that the functional DNA sequence is expressed.

4. A method of regulating the expression of a foreign functional DNA sequence which comprises cultivating a transformed host microorganism or cell which contains the recombinant DNA vector of Claim 2 under
15 appropriate conditions such that expression of the sequence is regulatable.

5. A method of preparing a transformed host microorganism comprising a recombinant DNA molecule comprising a Streptomyces gal operon P2 promoter
20 expression unit or any functional derivative thereof and a foreign functional DNA sequence operatively linked to such expression unit, which comprises transforming an appropriate host microorganism or cell with such molecule.

25 6. A method of preparing a transformed host microorganism or cell comprising a recombinant DNA vector comprising the molecule of Claim 5 and, optionally, additionally comprising a replicon which comprises transforming an appropriate host microorganism with
30 such vector.

7. A method of expressing a foreign functional DNA sequence which comprises cultivating a transformed microorganism or cell comprising a recombinant DNA vector comprising the molecule of Claim 5 and, optionally,
35 additionally comprising a replicon, under suitable con-

ditions such that the functional DNA sequence is expressed.

8. A method of preparing a transformed host microorganism or cell comprising a recombinant DNA molecule comprising a Streptomyces gal operon P1 promoter regulated region or any regulatable and functional derivative thereof and a foreign functional DNA sequence operatively linked to such regulated region, which comprises transforming an appropriate host micro-
10 organism or cell with such molecule.

9. A method of preparing a transformed host microorganism or cell comprising a recombinant DNA vector comprising the molecule of Claim 8 and, optionally, additionally comprising a replicon which comprises
15 transforming an appropriate host microorganism or cell with such vector.

10. A method of expressing a foreign functional DNA sequence which comprises cultivating a transformed host microorganism or cell comprising the recombinant
20 DNA vector of Claim 8 and, optionally, additionally comprising a replicon under suitable conditions such that the functional DNA sequence is expressed.

11. A method of regulating the expression of a foreign functional DNA sequence which comprises culti-
25 vating a transformed host microorganism or cell which contains a recombinant DNA vector comprising the molecule of Claim 8 and, optionally, additionally comprising a replicon, under appropriate conditions such that expression of the sequence is regulatable.

30 12. A method of preparing a transformed host microorganism or cell comprising a recombinant DNA molecule comprising a Streptomyces gal operon P2 promoter or any functional derivative thereof and a foreign functional DNA sequence operatively linked to the P2

promoter, which comprises transforming an appropriate host microorganism or cell with such molecule.

13. A method of preparing a transformed host microorganism or cell comprising a recombinant DNA vector comprising the molecule of Claim 12 and, optionally, additionally comprising a replicon, which comprises transforming an appropriate host microorganism with such vector.

14. A method of expressing a foreign functional DNA sequence which comprises cultivating a transformed host microorganism or cell comprising a recombinant DNA molecule of Claim 12 and, optionally, additionally comprising a replicon, under suitable conditions such that the functional DNA sequence is expressed.

15. A method of preparing a transformed host microorganism or cell comprising a recombinant DNA molecule comprising a Streptomyces gal operon P1 promoter or any regulatable and functional DNA sequence operatively linked to the P1 promoter, which comprises transforming an appropriate host microorganism or cell with such molecule.

16. A method of preparing a transformed host microorganism or cell comprising a recombinant DNA vector comprising the molecule of Claim 15 and, optionally, additionally comprising a replicon, which comprises transforming an appropriate host microorganism with such vector.

17. A method of expressing a foreign functional DNA sequence which comprises cultivating a transformed host microorganism or cell comprising a recombinant DNA vector comprising the molecule of Claim 15 and, optionally, additionally comprising a replicon, under suitable conditions such that the functional DNA sequence is expressed.

18. A method of regulating the expression of a foreign functional DNA sequence which comprises cultivating a transformed host microorganism or cell which contains a recombinant DNA vector comprising the molecule of Claim 15 and, optionally, additionally comprising a replicon, under appropriate conditions such that expression of the sequence is regulatable.

19. A method of preparing a transformed host microorganism or cell comprising a recombinant DNA molecule comprising a Streptomyces gal operon galE gene or any functional derivative thereof and a foreign functional DNA sequence operatively linked to the galE gene, which comprises transforming an appropriate host microorganism or cell with such molecule.

20. A method of preparing a transformed host microorganism or cell comprising a recombinant DNA molecule comprising a Streptomyces gal operon galT gene or any functional derivative thereof and a foreign functional DNA sequence operatively linked to the galT gene, which comprises transforming an appropriate host microorganism or cell with such molecule.

21. A method of preparing a transformed host microorganism or cell comprising a recombinant DNA molecule comprising a Streptomyces lividans gal operon galK gene or any functional derivative thereof and a foreign functional DNA sequence operatively linked to the galK gene, which comprises transforming an appropriate host microorganism or cell with such molecule.

22. A method of enabling a nongalactose utilizing host microorganism or cell to utilize galactose which comprises transforming such host with a recombinant DNA vector or molecule comprising Streptomyces gal operon, or any portion of the Streptomyces gal operon which is adequate to enable such transformed host to utilize galactose, or any functional derivative thereof.

⑤④ The gal operon of streptomyces.

⑤⑦ A recombinant DNA molecule comprising the *Streptomyces gal* operon *galK* gene; *galE* gene; *galT* gene; P1 promoter; P2 promoter; P2 promoter expression unit; P1 promoter regulated region, or the entire *Streptomyces gal* operon is prepared.
